Abstract

We study LHC phenomenology of mirage mediation scenario in which anomaly and modulus contributions to soft SUSY breaking terms are comparable to each other. A Monte Carlo study of mirage mediation, with model parameters $\alpha = 1$, $M_0 = 500$ GeV, $n_M = 1/2$, $n_H = 1$ and $\tan\beta = 10$, is presented. It is shown that masses of supersymmetric particles can be measured in a model independent way, providing information on SUSY breaking sector. In particular, the mass ratio of gluino to the lightest neutralino for the benchmark scenario is determined to be $1.9 \lesssim m_{\tilde{g}}/m_{\tilde{\chi}_1^0} \lesssim 3.1$, well reproducing theoretical input value of $m_{\tilde{g}}/m_{\tilde{\chi}_1^0} \simeq 2.5$ which is quite distinctive from the predictions $m_{\tilde{g}}/m_{\tilde{\chi}_1^0} \gtrsim 6$ of other SUSY scenarios in which gaugino masses are unified at the GUT scale. The model parameters of mirage mediation can be also determined from various kinematic distributions.

1 Introduction

Weak scale supersymmetry (SUSY) is one of the most promising candidates of new physics beyond the standard model (SM) [1]. It provides a solution for gauge hierarchy problem and complies with gauge coupling unification. Another nice feature of the SUSY theory with R-parity conservation is that the lightest supersymmetric particle (LSP) is a natural candidate for the non-baryonic dark matter (DM) in the universe.

SUSY phenomenology crucially depends on the masses of SUSY particles and their properties, which might result from spontaneous SUSY breaking in a hidden sector. The SUSY breaking is communicated to visible sector through some messenger interactions depending on models. Soft SUSY breaking terms of visible matter fields are then determined such that different SUSY breaking and mediating mechanism leads to different pattern of masses and properties of SUSY particles.

Recently Kachru *et al.* (KKLT) has provided a concrete set-up of string compactification, in which all moduli are fixed and Minkowski (or de Sitter) vacuum is achieved [2]. The KKLT-type moduli stabilization scenario leads to an interesting pattern of soft SUSY breaking terms, to which modulus and anomaly contributions are comparable to each other if gravitino mass $m_{3/2} \sim 10$ TeV [3]. A noticeable feature of the mixed modulus-anomaly mediation (*a.k.a* mirage mediation) is that soft masses are unified at a mirage messenger scale [4]

$$M_{mir} = M_{GUT} \left(\frac{m_{3/2}}{M_{Pl}} \right)^{\alpha/2} \quad (1)$$

with α representing the ratio of the anomaly to modulus mediation. The mirage messenger scale M_{mir} is hierarchically lower than M_{GUT} for a positive $\alpha \sim O(1)$. Such a low (mirage) unification scale for soft masses leads to a SUSY mass spectrum which is quite distinctive from those in other SUSY breaking scenarios such as mSUGRA, gauge mediation and anomaly mediation. Some phenomenological aspects of the mirage mediation have been investigated by several authors [5, 6].

In this paper, we investigate the LHC signatures of the mirage mediation performing a Monte Carlo study for a benchmark point in the scenario and show that SUSY particle masses can be determined in a model independent way, providing some valuable information on SUSY breaking sector. If the weak scale SUSY is realized in nature, SUSY particles would be produced copiously at the LHC [7, 8], which is scheduled to start in 2007. Gluinos and squarks, which are directly produced from the proton-proton collision, will decay to the LSP and SM particles in the end, with non-colored SUSY particles as intermediate states in general. The precise measurement of the masses of SUSY particles might be possible with reconstruction of the cascade decay chains [9, 10]. Kinematic edges and thresholds of various invariant mass distributions can be measured experimentally and then the SUSY particle masses would be determined in a model independent way. In turn,

SUSY breaking mechanism might be reconstructed from the measured SUSY spectrum and signatures.

This paper is organized as follows. The basic features of the mirage mediation are briefly described in section 2. The Monte Carlo study for a benchmark point is presented in section 3. Section 4 is devoted to the conclusions.

2 Mirage Mediation

In KKLT-type moduli stabilization scenario, the light modulus T which determines the SM gauge couplings is stabilized by non-perturbative effects and the SUSY-breaking source is sequestered from the visible sector. The non-perturbative stabilization of T by modulus superpotential results in a suppression of the modulus F component:

$$\frac{F^T}{T} \sim \frac{m_{3/2}}{\ln(M_{Pl}/m_{3/2})}, \quad (2)$$

which is comparable to anomaly mediated soft mass of $O(m_{3/2}/4\pi^2)$ for $m_{3/2}$ near the TeV scale. The soft terms of visible fields are then determined by the modulus mediation and the anomaly mediation if the SUSY breaking brane is sequestered from the visible sector. The soft terms of canonically normalized visible fields are given by

$$\mathcal{L}_{\text{soft}} = -\frac{1}{2}M_a\lambda^a\lambda^a - \frac{1}{2}m_i^2|\phi_i|^2 - \frac{1}{6}A_{ijk}y_{ijk}\phi_i\phi_j\phi_k + \text{h.c.}, \quad (3)$$

where λ^a are gauginos, ϕ_i are the scalar component of visible matter superfields Φ_i and y_{ijk} are the canonically normalized Yukawa couplings. For $F^T/T \sim m_{3/2}/4\pi^2$, the soft parameters at energy scale just below M_{GUT} are determined by the modulus-mediated and anomaly-mediated contributions which are comparable to each other. One then finds the boundary values of gaugino masses, trilinear couplings and sfermion masses at M_{GUT} are given by

$$\begin{aligned} M_a &= M_0 \left[1 + \frac{\ln(M_{Pl}/m_{3/2})}{16\pi^2} b_a g_a^2 \alpha \right], \\ A_{ijk} &= M_0 \left[(a_i + a_j + a_k) - \frac{\ln(M_{Pl}/m_{3/2})}{16\pi^2} (\gamma_i + \gamma_j + \gamma_k) \alpha \right], \\ m_i^2 &= M_0^2 \left[c_i - \frac{\ln(M_{Pl}/m_{3/2})}{16\pi^2} \theta_i \alpha - \left(\frac{\ln(M_{Pl}/m_{3/2})}{16\pi^2} \right)^2 \dot{\gamma}_i \alpha^2 \right], \end{aligned} \quad (4)$$

where α represents the anomaly to modulus mediation ratio:

$$\alpha \equiv \frac{m_{3/2}}{M_0 \ln(M_{Pl}/m_{3/2})}, \quad (5)$$

with M_0 the pure modulus mediated gaugino mass, while a_i and c_i parameterize the pattern of the pure modulus mediated soft masses. The one-loop beta function coefficient b_a , the anomalous dimension γ_i and its derivative $\dot{\gamma}_i$ and θ_i are defined by

$$\begin{aligned} b_a &= -3\text{tr}(T_a^2(\text{Adj})) + \sum_i \text{tr}(T_a^2(\phi_i)), \\ \gamma_i &= 2 \sum_a g_a^2 C_2^a(\phi_i) - \frac{1}{2} \sum_{jk} |y_{ijk}|^2, \\ \dot{\gamma}_i &= 8\pi^2 \frac{d\gamma_i}{d\ln\mu}, \\ \theta_i &= 4 \sum_a g_a^2 C_2^a(\phi_i) - \sum_{jk} |y_{ijk}|^2 (a_i + a_j + a_k), \end{aligned} \quad (6)$$

where the quadratic Casimir $C_2^a(\phi_i) = (N^2 - 1)/2N$ for a fundamental representation ϕ_i of the gauge group $SU(N)$, $C_2^a(\phi_i) = q_i^2$ for the $U(1)$ charge q_i of ϕ_i , and $\omega_{ij} = \sum_{kl} y_{ikl} y_{jkl}^*$ is assumed to be diagonal. The explicit expressions of b_a , γ_i , $\dot{\gamma}_i$ and θ in the MSSM are given in appendix A. In this prescription, generic mirage mediation is parameterized by

$$\alpha, M_0, a_i, c_i, \tan\beta, \quad (7)$$

where $\tan\beta$ is the ratio of the vacuum expectation values of the two neutral Higgs fields.

An interesting feature called mirage mediation arises from the soft masses of Eq. (4) at M_{GUT} , due to the correlation between the anomaly mediation and the RG evolution of soft parameters. The low energy gaugino masses are given by [4]

$$M_a(\mu) = M_0 \left[1 - \frac{1}{8\pi^2} b_a g_a^2(\mu) \ln \left(\frac{M_{\text{mir}}}{\mu} \right) \right] = \frac{g_a^2(\mu)}{g_a^2(M_{\text{mir}})} M_0, \quad (8)$$

implying that the gaugino masses are unified at M_{mir} , while the gauge couplings are unified at M_{GUT} . If the y_{ijk} is small or $a_i + a_j + a_k = c_i + c_j + c_k = 1$, the low energy values of A_{ijk} and m_i^2 are given by [4]

$$\begin{aligned} A_{ijk}(\mu) &= M_0 \left[a_i + a_j + a_k + \frac{1}{8\pi^2} (\gamma_i(\mu) + \gamma_j(\mu) + \gamma_k(\mu)) \ln \left(\frac{M_{\text{mir}}}{\mu} \right) \right], \\ m_i^2(\mu) &= M_0^2 \left[c_i - \frac{1}{8\pi^2} Y_i \left(\sum_j c_j Y_j \right) g_Y^2(\mu) \ln \left(\frac{M_{GUT}}{\mu} \right) \right. \\ &\quad \left. + \frac{1}{4\pi^2} \left\{ \gamma_i(\mu) - \frac{1}{2} \frac{d\gamma_i(\mu)}{d\ln\mu} \ln \left(\frac{M_{\text{mir}}}{\mu} \right) \right\} \ln \left(\frac{M_{\text{mir}}}{\mu} \right) \right], \end{aligned} \quad (9)$$

where Y_i is the $U(1)_Y$ charge of ϕ_i . Therefore, the first- and second-generation sfermion masses are also unified at the M_{mir} scale if the modulus-mediated squark and slepton masses have a common value, i.e. $c_{\tilde{q}} = c_{\tilde{\ell}} (\equiv c_M)$.

Phenomenology of mirage mediation is quite sensitive to the anomaly to modulus mediation ratio α as well as the parameters a_i and c_i [4, 5, 6]. When α increases from zero to a positive value of order unity, the nature of the neutralino LSP is changed from bino-like to Higgsino-like via a bino-Higgsino mixing region. This feature can be understood from the dependence of the gaugino masses on α . The gluino mass M_3 decreases as α increases, while the bino mass M_1 increases. Smaller M_3 then leads to smaller $|m_{H_u}^2|$ and Higgsino mass parameter $|\mu|$ at the weak scale through smaller stop mass square. While the gaugino masses are not sensitive to a_i and c_i , the low energy squark, slepton and Higgs masses depend on those parameters through their boundary values at M_{GUT} and their RG evolutions and the mass mixing induced by the low energy A parameters.

For the original KKLT compactification of type IIB string theory [2], one finds that $\alpha = 1$, $a_i = c_i = 1 - n_i$, where n_i are modular weights of the visible sector matter fields depending on the origin of the matter fields. The corresponding mirage messenger scale for $\alpha = 1$ is given by $M_{mir} \sim 3 \times 10^9$ GeV. Such an intermediate (mirage) unification scale which is hierarchically smaller than M_{GUT} , leads to quite a degenerated sparticle mass spectrum at EW scale, compared to that for mSUGRA-type pure modulus mediation ($\alpha = 0$). In this paper, we will consider the intermediate scale mirage mediation ($\alpha = 1$) as a benchmark scenario for a detailed Monte Carlo study of LHC phenomenology.

3 Collider signatures

3.1 A benchmark point

We perform a Monte Carlo study for LHC signatures of mirage mediation with the following model parameters;

$$\alpha = 1, \quad M_0 = 500 \text{ GeV}, \quad a_M = c_M = 1/2, \quad a_H = c_H = 0, \quad \tan\beta = 10, \quad (10)$$

where c_M is a common parameter which parameterize the pattern of the pure modulus mediated masses for squarks and sleptons and c_H for soft Higgses. This choice of model parameters is denoted as a blue dot on the (α, M_0) plane of Fig.1, which was taken from the figure 12 (c) in ref.[6]. In the Fig.1, the magenta stripe corresponds to the parameter region giving a thermal relic density consistent with the recent WMAP observation [11], *i.e.* $0.085 < \Omega_{DM} h^2 < 0.119$. The benchmark point is also consistent with constraints on particle spectra and $b \rightarrow s\gamma$ branching ratio.

The SUSY particle mass spectrum at the electroweak(EW) scale was computed by solving the RG equations with the model parameter set (10). For the gluino and the first two generation squark masses, we find

$$m_{\tilde{g}} = 884.4 \text{ GeV}, \quad m_{\tilde{d}_L(\tilde{u}_L)} = 776.0 \text{ (771.9) GeV}, \quad m_{\tilde{d}_R(\tilde{u}_R)} = 733.5 \text{ (741.8) GeV}, \quad (11)$$

while the masses of the third generation squarks are

$$m_{\tilde{b}_{1(2)}} = 703.9 \text{ (734.6) GeV}, \quad m_{\tilde{t}_{1(2)}} = 545.3 \text{ (782.0) GeV} \quad (12)$$

Figure 1: *Parameter space (α, M_0) with $a_H = c_H = 0$, $a_M = c_M = 1/2$ and $\tan\beta = 10$. The blue point corresponds to our benchmark point, which satisfy relic density bound of WMAP observation and is consistent with other experimental constraints on particle masses and $b \rightarrow s\gamma$ branching ratio.*

On the other hand, the slepton and sneutrino masses are

$$m_{\tilde{e}_{R(L)}} = 382.0 \text{ (431.5) GeV}, \quad m_{\tilde{\tau}_{1(2)}} = 378.9 \text{ (435.4) GeV}, \quad m_{\tilde{\nu}_L} = 424.1 \text{ GeV}. \quad (13)$$

For the neutralino and chargino masses, we have

$$m_{\tilde{\chi}_{1,2,3,4}^0} = \{355.1, 416.1, 478.7, 535.6\} \text{ GeV}, \quad m_{\tilde{\chi}_{1,2}^\pm} = \{408.2, 533.5\} \text{ GeV}, \quad (14)$$

which correspond to the following bino, wino and Higgsino masses at electroweak scale,

$$M_1 = 367 \text{ GeV}, \quad M_2 = 461 \text{ GeV}, \quad \mu = 475 \text{ GeV} \quad (\text{for } \tan\beta = 10). \quad (15)$$

Finally, Higgs masses are given by

$$m_h = 115 \text{ GeV}, \quad m_H = 528.6 \text{ GeV}, \quad m_A = 528.3 \text{ GeV}, \quad m_{H^\pm} = 534.4 \text{ GeV}. \quad (16)$$

Fig. 2(a) shows the mass spectrum for the benchmark point. For comparison, we also show the spectrum of a mSUGRA point, which gives the same mass of neutralino LSP as

3.2 Monte Carlo Events

A Monte Carlo event sample of the SUSY signals for proton-proton collision at an energy of 14 TeV has been generated by PYTHIA 6.4 [12]. The event sample corresponds to 30 fb^{-1} of integrated luminosity, which is expected with the 3 year running of the LHC at low luminosity. We have also generated SM background events *i.e.*, $t\bar{t}$ events equivalent to 30 fb^{-1} of integrated luminosity and also $W/Z + \text{jet}$, $WW/WZ/ZZ$ and QCD events, with less equivalent luminosity, in five logarithmic p_T bins for $50 \text{ GeV} < p_T < 4000 \text{ GeV}$. The generated events have been further processed with a modified version of the fast detector simulation program PGS (Pretty Good Simulation)[13], which approximate an ATLAS- or CMS-like detector with reasonable efficiencies and fake rates.

The total production cross section for SUSY events at the LHC is $\sim 6.1 \text{ pb}$ for the benchmark point, corresponding to $\sim 1.8 \times 10^5$ events with 30 fb^{-1} luminosity. Squarks and gluinos are expected to be copiously produced at the LHC, if $m_{\tilde{q}}, m_{\tilde{g}} \lesssim 1 \text{ TeV}$. With the masses of gluino and squarks in the Eq. (11), the production cross sections for the $\tilde{g}\tilde{g}$, $\tilde{g}\tilde{q}$, and $\tilde{q}\tilde{q}$ pairs are about 0.3 pb, 2.7 pb and 2.0 pb, respectively, such that the gluino-squark pair production and the squark pair production dominate.

The produced squarks and gluinos decay generally in multistep. In the recent past, the following cascade decay chain of squark has been exploited in detail [9, 10];

$$\tilde{q}_L \rightarrow \tilde{\chi}_2^0 q \rightarrow \tilde{l}_R^\pm l^\mp q \rightarrow \tilde{\chi}_1^0 l^+ l^- q, \quad (17)$$

especially in mSUGRA framework. It was shown that it would be possible to reconstruct both upper edges for the $l^+ l^-$, $l^+ l^- q$, and $l^\pm q$ mass distribution and a lower edge for the $l^+ l^- q$ mass coming from backwards decays of the $\tilde{\chi}_2^0$ in the $\tilde{q}_L$ rest frame. Those edge values of the mass distributions are given by the following analytic formulae, in terms of the particle masses involved in the decay chain;

$$M_{ll}^{max} = \left[\frac{(m_{\tilde{\chi}_2^0}^2 - m_{l_R}^2)(m_{l_R}^2 - m_{\tilde{\chi}_1^0}^2)}{m_{l_R}^2} \right]^{1/2}, \quad (18)$$

$$M_{llq}^{max} = \left[\frac{(m_{\tilde{q}_L}^2 - m_{\tilde{\chi}_2^0}^2)(m_{\tilde{\chi}_2^0}^2 - m_{\tilde{\chi}_1^0}^2)}{m_{\tilde{\chi}_2^0}^2} \right]^{1/2}, \quad (19)$$

$$M_{lq}^{max}(high) = \left[\frac{(m_{\tilde{q}_L}^2 - m_{\tilde{\chi}_2^0}^2)(m_{\tilde{\chi}_2^0}^2 - m_{l_R}^2)}{m_{\tilde{\chi}_2^0}^2} \right]^{1/2}, \quad (20)$$

$$\begin{aligned} (M_{llq}^{min})^2 &= \frac{1}{4m_{\tilde{\chi}_2^0}^2 m_{l_R}^2} [-m_{\tilde{\chi}_1^0}^2 m_{\tilde{\chi}_2^0}^4 + 3m_{\tilde{\chi}_1^0}^2 m_{\tilde{\chi}_2^0}^2 m_{l_R}^2 - m_{\tilde{\chi}_2^0}^4 m_{l_R}^2 - m_{\tilde{\chi}_2^0}^2 m_{l_R}^4 \\ &- m_{\tilde{\chi}_1^0}^2 m_{\tilde{\chi}_2^0}^2 m_{\tilde{q}_L}^2 - m_{\tilde{\chi}_1^0}^2 m_{l_R}^2 m_{\tilde{q}_L}^2 + 3m_{\tilde{\chi}_2^0}^2 m_{l_R}^2 m_{\tilde{q}_L}^2 - m_{l_R}^4 m_{\tilde{q}_L}^2 \\ &+ (m_{\tilde{\chi}_2^0}^2 - m_{\tilde{q}_L}^2) \sqrt{(m_{\tilde{\chi}_1^0}^4 + m_{l_R}^4)(m_{\tilde{\chi}_2^0}^2 + m_{l_R}^2)^2 + 2m_{\tilde{\chi}_1^0}^2 m_{l_R}^2 (m_{\tilde{\chi}_2^0}^4 - 6m_{\tilde{\chi}_2^0}^2 m_{l_R}^2 + m_{l_R}^4)}]. \end{aligned} \quad (21)$$

We can also measure the upper edge of the distribution of the *smaller* of the two possible lq masses formed by combining two leptons with a quark jet [14];

$$\begin{aligned}
M_{lq}^{max}(low) &= \left[\frac{(m_{\tilde{q}_L}^2 - m_{\tilde{\chi}_2^0}^2)(m_{\tilde{e}_R}^2 - m_{\tilde{\chi}_1^0}^2)}{2m_{\tilde{e}_R}^2 - m_{\tilde{\chi}_1^0}^2} \right]^{1/2} \quad \text{for } 2m_{\tilde{e}_R}^2 - (m_{\tilde{\chi}_1^0}^2 + m_{\tilde{\chi}_2^0}^2) < 0. \\
&= \left[\frac{(m_{\tilde{q}_L}^2 - m_{\tilde{\chi}_2^0}^2)(m_{\tilde{\chi}_2^0}^2 - m_{\tilde{e}_R}^2)}{m_{\tilde{\chi}_2^0}^2} \right]^{1/2} \quad \text{for } 2m_{\tilde{e}_R}^2 - (m_{\tilde{\chi}_1^0}^2 + m_{\tilde{\chi}_2^0}^2) > 0. \quad (22)
\end{aligned}$$

From the kinematic edge measurements, the SUSY particle masses might be then determined without relying on a model. For the benchmark point, we can notice that $m_{\tilde{\chi}_2^0} > m_{\tilde{e}_R}$. Therefore, the cascade decay chain (17) is indeed open so that the well-established method of the kinematic edge measurements can be applied to our case.

In order to reduce the SM background to a negligible level, we apply the following event selection cuts;

- (1) At least three jets with $P_{T1} > 200$ GeV and $P_{T2,3} > 50$ GeV.
- (2) Missing transverse energy, $E_T^{miss} > 200$ GeV.
- (3) $E_T^{miss}/M_{eff} > 0.2$, where $M_{eff} \equiv P_{T1} + P_{T2} + P_{T3} + P_{T4} + E_T^{miss} + \sum_{leptons} P_{Ti}$
- (4) At least two isolated leptons of opposite charge, with $P_T > 10$ GeV and $|\eta| < 2.5$.
- (5) Transverse sphericity $S_T > 0.1$.
- (6) No b-jets.

Following the analysis in Ref.[9], we have then calculated various invariant mass distributions for the benchmark point. The dilepton invariant mass distribution is shown in the Fig. 3. Here, the $e^+e^- + \mu^+\mu^- - e^\pm\mu^\mp$ combination was used in order to cancel contributions for two independent decays and reduce combinatorial background. The SM backgrounds which denoted as blue histogram on the plot, are negligible with the above event selection cuts, as expected from previous studies [7, 9]. We find a clear end point in the dilepton mass distribution. A Gaussian-smeared triangular fit to the distribution gives $M_{ll}^{max} = 60.61 \pm 0.13$ GeV, which is $\sim 0.3\%$ lower than the calculated value of $M_{ll}^{max} = 60.8$ GeV for the decays $\tilde{\chi}_2^0 \rightarrow \tilde{l}_R l^\pm \rightarrow \tilde{\chi}_1^0 l^+ l^-$.

The dilepton plus jet invariant mass M_{llq} has been also calculated by combining the dilepton with one of the two hardest P_T jets. The two hardest jets are expected to come from squark decays $\tilde{q} \rightarrow \tilde{\chi} q$ as dominant production processes result in a pair of squark. The distribution for the smaller of the two possible llq masses is shown in Fig. 4(a). The upper edge value of the l^+l^-q masses is given by $M_{llq}^{max} = 341.5 \pm 3.6$ GeV, which is obtained from a Gaussian smeared fit plus a linear background. The fitted value is consistent with the calculated value of $M_{llq}^{max} = 341.4$ GeV for the decays $\tilde{q}_L \rightarrow \tilde{\chi}_2^0 q \rightarrow \tilde{l}_R^\pm l^\mp q \rightarrow \tilde{\chi}_1^0 l^+ l^- q$ (with $m_{\tilde{q}_L} = 776$ GeV).

Now, we further require that one M_{llq} should be less than 350 GeV and the other greater. Two $l^\pm q$ masses are then calculated using the combination of l^+l^-q with the smaller M_{llq} (< 350 GeV). Fig. 4(b) shows the mass distribution of the *larger* of the

Figure 3: Dilepton ($e^+e^- + \mu^+\mu^- - e^\pm\mu^\mp$) invariant mass distributions for the benchmark point. Blue histogram corresponds to SM background.

two $l^\pm q$ system. A fit to the mass distribution near the end point is also shown, which yield an upper edge value $M_{lq}^{max}(high) = 258.6 \pm 4.8$ GeV, which is consistent with the calculated value of $M_{lq}^{max}(high) = 259.7$ GeV.

The mass distribution of the *smaller* of the two M_{lq} is shown in Fig. 4(c). The upper edge value of the distribution from a linear fit is given by $M_{lq}^{max}(low) = 227.6 \pm 3.3$ GeV, which is consistent with the calculated value of $M_{lq}^{max}(low) = 226.5$ GeV.

The lower edge for l^+l^-q mass can be reconstructed from the larger of the two possible l^+l^-q masses, with additional requirement $M_{ll}^{max}/\sqrt{2} < M_{ll} < M_{ll}^{max}$. The resulting distribution is shown in Fig. 4(d). A fit to the distribution gives $M_{llq}^{min} = 145.3 \pm 2.8$ GeV, which is consistent with the generated value $M_{llq}^{min} = 145.4$ GeV.

From the above five edge measurements for the $\tilde{q}_L$ cascade decays (17), we can determine the masses of $\tilde{q}_L$, $\tilde{l}_R$, $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^0$ using the eqs. (18-22).

With given masses of $\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0$, we can get information for gluino and squark masses from the following gluino decay into right-handed squark plus quark;

$$\tilde{g} \rightarrow \tilde{q}_R q \rightarrow \tilde{\chi}_1^0 q q. \quad (23)$$

Figure 4: Distributions for (a) the smaller of the two M_{llq} , (b) the larger of two M_{lq} , (c) the smaller of the two M_{lq} , and (d) the larger of the two M_{llq} with $M_{ll} > M_{ll}^{max}/\sqrt{2}$.

The maximal value of the two jet invariant mass for the gluino decays (23) is given by

$$M_{qq}^{max} = \left[\frac{(m_{\tilde{g}}^2 - m_{\tilde{q}_R}^2)(m_{\tilde{q}_R}^2 - m_{\tilde{\chi}_1^0}^2)}{m_{\tilde{q}_R}^2} \right]^{1/2}. \quad (24)$$

At the LHC, gluino would be produced mainly from $\tilde{g}\tilde{q}$ or $\tilde{g}\tilde{g}$ pair production. In order to obtain event sample for the gluino decay (23), the following event selection cuts are imposed;

- (1) At least 3 jets with $P_{T1} > 200$ GeV, $P_{T2} > 150$ GeV and $P_{T3} > 100$ GeV.
- (2) $E_T^{miss} > 350$ GeV and $E_T^{miss}/M_{eff} > 0.25$.
- (3) Transverse sphericity $S_T > 0.15$.

Figure 5: Dijet invariant mass distribution (a) without dilepton and (b) with dilepton.

(4) No b-jets and No leptons.

In the selection cuts, we required rather hard $P_{T3} > 100$ GeV in order to reduce $\tilde{q}\tilde{q}$ production events. After the selection cuts, we calculate dijet invariant mass M_{qq} using the three hardest jets. The smallest M_{qq} among the three possible combinations is then shown in Fig. 5 (a). The M_{qq} distribution is fitted near end point by a Gaussian smeared linear function with a linear background. The resulting edge value is given by $M_{qq}^{max} = 431.1 \pm 32.1$ GeV, which is consistent with the calculated one $M_{qq}^{max} = 432.4$ GeV (with $m_{\tilde{q}_R} = 733.5$ GeV).

Additional information on $m_{\tilde{g}}$ and $m_{\tilde{q}_R}$ might be provided by the following cascade decay of gluino,

$$\tilde{g} \rightarrow \tilde{q}_R q \rightarrow \tilde{\chi}_2^0 q q (\rightarrow \tilde{\chi}_1^0 l l q q), \quad (25)$$

for which the upper edge value of the two jet invariant mass distribution is given by

$$M_{qq}^{max}(ll) = \left[\frac{(m_{\tilde{g}}^2 - m_{\tilde{q}_R}^2)(m_{\tilde{q}_R}^2 - m_{\tilde{\chi}_2^0}^2)}{m_{\tilde{q}_R}^2} \right]^{1/2}. \quad (26)$$

In the gluino cascade decay (25), we consider the right-handed squark decay into $\tilde{\chi}_2^0$ rather than $\tilde{\chi}_1^0$, where the $\tilde{\chi}_2^0$ further undergoes the dileptonic decay. In the benchmark point, branching ratio $BR(\tilde{q}_R \rightarrow \tilde{\chi}_2^0 q) = 11\%$ is comparable to $BR(\tilde{q}_L \rightarrow \tilde{\chi}_2^0 q) = 18.5\%$. This is because the gaugino masses are quite degenerated (*i.e.* $M_2/M_1 \sim 1.26$) at EW scale

so that $\tilde{\chi}_2^0$ has sizable bino-component in the benchmark point, which is in contrast to the typical mSUGRA case where $\tilde{\chi}_2^0$ is almost wino-like and therefore $BR(\tilde{q}_R \rightarrow \tilde{\chi}_2^0 q)$ is negligible. Furthermore, the gluino branching ratio of $BR(\tilde{g} \rightarrow \tilde{q}_R q) \simeq 19\%$ is larger than $BR(\tilde{g} \rightarrow \tilde{q}_L q) \simeq 11.2\%$ for $q=u,d$ so that the decay chain of $\tilde{g} \rightarrow \tilde{q}_R q \rightarrow \tilde{\chi}_2^0 qq$ is comparable to that of $\tilde{g} \rightarrow \tilde{q}_L q \rightarrow \tilde{\chi}_2^0 qq$. Considering the squark masses that $m_{\tilde{q}_R} < m_{\tilde{q}_L}$, the upper edge value of two jet invariant mass for $\tilde{\chi}_2^0 qq$ events is essentially determined by the Eq. (26), which involves $m_{\tilde{q}_R}$ rather than $m_{\tilde{q}_L}$.

In order to select events which include decay chain (25), we require

- (1) At least 3 jets with $P_{T1} > 100$ GeV and $P_{T2,3} > 50$ GeV
- (2) $E_T^{miss} > 200$ GeV and $M_{eff}/E_T^{miss} > 0.2$
- (3) At least two isolated leptons with opposite charge
- (4) $M_{ll} < 61$ GeV and the smallest $M_{llq} < 350$ GeV
- (5) Transverse sphericity $S_T > 0.1$
- (6) No b-jets

After the selection cut, dijet invariant mass was calculated using the jet, which gives the smallest M_{llq} , with third and fourth (if any) energetic jets. The smaller of the two possible dijet mass is then shown in Fig. 5 (b). A fit to the distribution gives $M_{qq}^{max}(ll) = 405.7 \pm 8.6$ GeV, which is consistent with the calculated value of $M_{qq}^{max}(ll) = 406.9$ GeV (with $m_{\tilde{q}_R} = 733.5$ GeV).

The upper edge measurements of two dijet invariant masses provide lower limits on the gluino and squark masses and a strong correlation between $m_{\tilde{g}}$ and $m_{\tilde{q}_R}$, but without constraint on the upper limit on the masses. In order to further constrain the right-handed squark mass, we consider squark pair production and their subsequent decay into two quarks plus two LSPs;

$$\tilde{q}_{1R}\tilde{q}_{2R} \rightarrow q_1\tilde{\chi}_1^0 q_2\tilde{\chi}_1^0, \quad (27)$$

and construct another variable M_{T2} [15], which is defined by

$$M_{T2}^2 \equiv \min_{\mathbf{p}_{T1}^\chi + \mathbf{p}_{T2}^\chi = \mathbf{p}_T^{miss}} [\max\{m_T^2(\mathbf{p}_T^{q1}, \mathbf{p}_{T1}^\chi), m_T^2(\mathbf{p}_T^{q2}, \mathbf{p}_{T2}^\chi)\}], \quad (28)$$

where

$$m_{T2}^2(\mathbf{p}_T^q, \mathbf{k}_T^\chi) \equiv m_q^2 + m_\chi^2 + 2(E_T^q E_T^\chi - \mathbf{p}_T^q \cdot \mathbf{k}_T^\chi), \quad (29)$$

$$E_T^q = \sqrt{|\mathbf{p}_T^q|^2 + m_q^2}, \quad E_T^\chi = \sqrt{|\mathbf{k}_T^\chi|^2 + m_\chi^2}. \quad (30)$$

Here, $\mathbf{p}_T^{q1}$ and $\mathbf{p}_T^{q2}$ denote the transverse momentum of quark-jets from the squark decays and $\mathbf{p}_T^{miss}$ is the observed missing transverse momentum and m_χ is an estimate of the lightest neutralino mass. The M_{T2} distribution has an endpoint at the squark mass $m_{\tilde{q}_R}$

Figure 6: (a) The M_{T2} distribution with the input value of $m_\chi = 350$ GeV as an example. (b) A relation between $m_{\tilde{q}_R}$ and $m_{\tilde{\chi}_1^0}$ from the M_{T2} analysis.

when the input m_χ is equal to the correct $m_{\tilde{\chi}_1^0}$ value. In general we obtain a relation between $m_{\tilde{q}_R}$ and $m_{\tilde{\chi}_1^0}$.

In order to have event sample for the squark pair production and their subsequent decay (27), the following event selection cuts are required;

- (1) At least two jets with $P_{T1} > 300$ GeV, $P_{T2} > 50$ GeV
- (2) $E_T^{miss} > 200$ GeV, $M_{eff}/E_T^{miss} > 0.3$
- (3) Transverse sphericity $S_T > 0.15$
- (4) No leptons, no b-jets.

Fig. 6(a) shows an example of M_{T2} distribution with an input value of $m_\chi = 350$ GeV. From a fit to the distribution, we obtain $m_{\tilde{q}_R} = 749 \pm 12$ GeV for the example. A general relation between $m_{\tilde{q}_R}$ and $m_{\tilde{\chi}_1^0}$ from the M_{T2} analysis is shown in Fig. 6(b).

Now we can determine six SUSY particle masses, $m_{\tilde{\chi}_1^0}$, $m_{\tilde{\chi}_2^0}$, $m_{\tilde{l}_R}$, $m_{\tilde{q}_L}$, $m_{\tilde{g}}$ and $m_{\tilde{q}_R}$, from the various kinematic distributions we considered so far. In order to scan possible values of SUSY particle masses, random numbers for $m_{\tilde{\chi}_2^0}$, $m_{\tilde{l}_R}$, $m_{\tilde{q}_L}$, $m_{\tilde{q}_R}$, and $m_{\tilde{g}}$ were generated within some ranges around their nominal values, while $m_{\tilde{\chi}_1^0}$ values were calculated with the measured M_{ll}^{max} value. The chi-square from the various kinematic observables with their errors was calculated to determine the probability for each set of masses. Fig. 7 shows the probability distribution of (a) $m_{\tilde{\chi}_1^0}$, (b) $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$, (c) $m_{\tilde{l}_R} - m_{\tilde{\chi}_1^0}$ (d) $m_{\tilde{q}_L} - m_{\tilde{\chi}_1^0}$, (e) $m_{\tilde{q}_R} - m_{\tilde{\chi}_1^0}$ and (f) $m_{\tilde{g}} - m_{\tilde{\chi}_1^0}$, respectively. While the $\tilde{\chi}_1^0$ mass is de-

Figure 7: Probability distribution of (a) $m_{\tilde{\chi}_1^0}$, (b) $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$, (c) $m_{\tilde{l}_R} - m_{\tilde{\chi}_1^0}$, (d) $m_{\tilde{q}_L} - m_{\tilde{\chi}_1^0}$, (e) $m_{\tilde{q}_R} - m_{\tilde{\chi}_1^0}$ and (f) $m_{\tilde{g}} - m_{\tilde{\chi}_1^0}$.

terminated as

$$m_{\tilde{\chi}_1^0} = 356_{-95}^{+220} \text{ GeV}, \quad (31)$$

the differences between particle masses are rather well constrained,

$$\begin{aligned} m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0} &= 60.8 \pm 0.1 \text{ GeV}, \quad m_{\tilde{l}_R} - m_{\tilde{\chi}_1^0} = 27.0 \pm 0.6 \text{ GeV}, \quad m_{\tilde{q}_L} - m_{\tilde{\chi}_1^0} = 436 \pm 22 \text{ GeV}, \\ m_{\tilde{q}_R} - m_{\tilde{\chi}_1^0} &= 393 \pm 16 \text{ GeV}, \quad m_{\tilde{g}} - m_{\tilde{\chi}_1^0} = 536 \pm 15 \text{ GeV}, \end{aligned} \quad (32)$$

respectively. The central values for the estimated masses are consistent with the generated ones. And the range for the mass ratio between gluino and the lightest neutralino is given by

$$1.9 \lesssim \frac{m_{\tilde{g}}}{m_{\tilde{\chi}_1^0}} \lesssim 3.1 \quad (\text{reduced } \chi^2 < 1), \quad (33)$$

which is quite distinctive from the typical predictions *i.e.*, $m_{\tilde{g}}/m_{\tilde{\chi}_1^0} \gtrsim 6$ of the other SUSY scenarios in which gaugino masses are unified at GUT scale.

Figure 8: Probability distribution of (a) α , (b) M_0 , (c) c_M , and (d) c_H .

So far we have considered 'model-independent' measurements of SUSY particle masses. We can also determine the model parameters of mirage mediation scenario from the kinematic endpoint measurements. As mentioned in section 2, generic mirage mediation is parameterized by M_0, α, a_i, c_i and $\tan\beta$. Here, we assume that visible sfermion fields have a universal parameter $c_M (= a_M)$ while the corresponding parameter for Higgs fields is given by $c_H (= a_H)$. The model is then described by five parameters M_0, α, c_M, c_H and $\tan\beta$. From the Eq. (8) and (9) we can see that the gaugino and the first generation sfermion masses at low energy scale are essentially determined by M_0, α and c_M . Therefore, we can determine the model parameters M_0, α and c_M from the measured $m_{\tilde{g}}, m_{\tilde{q}}$ and $m_{\tilde{l}_R}$.

With given values of M_0, α and c_M , the parameters c_H and $\tan\beta$ might be obtained from the measured $m_{\tilde{\chi}_1^0}$ and $m_{\tilde{\chi}_2^0}$. We have scanned five model parameters in certain ranges and calculated the χ^2 from the calculated and measured kinematic edge values, in order to constraint the model parameters. Fig. 8 shows probability distributions for α, M_0, c_M and c_H , resulting in the following values of the parameters:

$$\alpha = 0.98 \pm 0.03, \quad M_0 = 492 \pm 22 \text{ GeV}, \quad c_M = 0.48 \pm 0.01, \quad c_H = 0.02 \pm 0.05. \quad (34)$$

The model parameters are determined quite accurately, except $\tan\beta$ whose value is not so well constrained because neutralino masses depend on it rather mildly. The resulting central values of the parameters well agree with the input values of Eq (10).

4 Conclusions

In this paper we have investigated LHC signatures of mirage mediation by performing a Monte Carlo study for a benchmark point in which anomaly and modulus contribution to soft SUSY breaking terms are comparable to each other.

The benchmark point has characteristic features of mirage mediation such as rather degenerated gaugino masses at EW scale ($M_1 : M_2 : M_3 \simeq 1 : 1.26 : 2.3$) and enhanced Wino- and Higgsino- components of the lightest neutralino, comparing to typical mSUGRA case. Non-negligible wino and Higgsino components of the LSP leads to right amount of thermal relic density which is compatible to WMAP data, though the LSP mass is rather large ($m_{\tilde{\chi}_1^0} \sim 355 \text{ GeV}$). Rather degenerated gaugino masses at EW scale lead to the mass ratio of gluino to the lightest neutralino $m_{\tilde{g}}/m_{\tilde{\chi}_1^0} \sim 2.5$, which is quite distinctive from the typical predictions *i.e.*, $m_{\tilde{g}}/m_{\tilde{\chi}_1^0} \gtrsim 6$ of the SUSY scenarios which have gaugino mass unification at the GUT scale.

For the benchmark point, the ‘golden’ decay chain of squark (17) is open, allowing model independent measurement of SUSY particle masses such as $m_{\tilde{q}_L}, m_{\tilde{l}_R}, m_{\tilde{\chi}_2^0}$ and $m_{\tilde{\chi}_1^0}$. We also determined gluino and squark masses from various gluino and squark decays. The SUSY particle masses are then determined in a model independent way, giving valuable information on SUSY breaking sector. In particular, the measured ratio of $1.9 \lesssim m_{\tilde{g}}/m_{\tilde{\chi}_1^0} \lesssim 3.1$ well reproduce the theoretical input value $m_{\tilde{g}}/m_{\tilde{\chi}_1^0} \simeq 2.5$ of the benchmark point. Therefore, the benchmark scenario may be distinguishable experimentally from other SUSY scenario in which gaugino masses are unified at the GUT scale. Model parameters were also obtained with small errors, from a global fit to the observables with their estimated errors. The resulting central values of the model parameters well agree with the input values for the benchmark point.
